1   Introduction

Sushi is an R package for plotting genomic data stored in multiple common genomic formats including bed, bedpe, bedgraph format. The package was designed to be very flexible to allow for combinations of plots into multipanel figures that can include plots made by Sushi, R basecode, or other R packages. Sushi allows for simple flexible plotting of gene structures, transcript structures, sequencing tracks, ChIP-seq peaks, chromatin interactions, GWAS results and other commen genomic data types. This vignette shows some examples of the functions included in Sushi to get you started with plotting these diverse data types.

2   Data

2.1   Data types

Sushi accepts 4 types of genomic data as input. These include:

- bed format: 3-6 columns (chromosome, start, stop, name, score, strand)

- bedpe format: 6-10 columns (chromosome1, start1, stop1, chromosome2, start2, stop2,name, score, strand1, strand2)

- bedgraph format: 4 columns (chromosome, start, stop, score)

- interaction matrix: This is matrix in which row and column names are genomic coordiates and matrix values are some tye of interaction score.

** strands can be represented as 1 or -1 or "+" and "-".

** Some functions may require additional information depending on the plot and features desired.

2.2   Example datasets

To illustrate how Sushi works, we have included several publicaly available data sets in the package Sushi. The data types include RNA-seq, ChIP-seq, ChIA-PET, and HiC data:

`Sushi_5C.bedpe`	Sanyal et al. [7]
`Sushi_ChIAPET_pol2.bedpe`	Li et al. [4]
`Sushi_ChIPExo_CTCF.bedgraph`	Rhee and Pugh [6]
`Sushi_ChIPSeq_CTCF.bedgraph`	The ENCODE Project Consortium [8]
`Sushi_ChIPSeq_pol2.bed`	The ENCODE Project Consortium [8]
`Sushi_ChIPSeq_pol2.bedgraph`	The ENCODE Project Consortium [8]
`Sushi_ChIPSeq_severalfactors.bed`	The ENCODE Project Consortium [8]
`Sushi_DNaseI.bedgraph`	Neph et al. [5]
`Sushi_GWAS.bed`	International Consortium for Blood Pressure [3]
`Sushi_HiC.matrix`	Dixon et al. [2]
`Sushi_RNASeq_K562.bedgraph`	The ENCODE Project Consortium [8]
`Sushi_genes.bed`	Biomart [1]
`Sushi_hg18_genome`	Biomart [1]
`Sushi_transcripts.bed`	The ENCODE Project Consortium [8]

These data sets can be loaded using the following commands:

```
> library('Sushi')
> Sushi_data = data(package = 'Sushi')
> data(list = Sushi_data$results[,3])
```

To see which data sets are loaded

```
> Sushi_data$results[,3]
```

```
 [1] "Sushi_5C.bedpe"                  "Sushi_ChIAPET_pol2.bedpe"
 [3] "Sushi_ChIPExo_CTCF.bedgraph"     "Sushi_ChIPSeq_CTCF.bedgraph"
 [5] "Sushi_ChIPSeq_pol2.bed"          "Sushi_ChIPSeq_pol2.bedgraph"
 [7] "Sushi_ChIPSeq_severalfactors.bed" "Sushi_DNaseI.bedgraph"
 [9] "Sushi_GWAS.bed"                  "Sushi_HiC.matrix"
[11] "Sushi_RNASeq_K562.bedgraph"      "Sushi_genes.bed"
[13] "Sushi_hg18_genome"               "Sushi_transcripts.bed"
```

3 Functions

3.1 Functions overview

Sushi functions can be broken down into 3 categories: plotting, annotating, zooming, and coloring. Plotting functions generate a basic plot object using the data. Annotating functions add information to the plots such as an x-axis labeling the genomic region or a legend describing the values represented by different colors. Zooming functions allow for highlighting and zooming of genomic regions, which are of particular use for multipanel plots generated with base R functions `mfrow()` or `layout()`. The coloring functions provide simple tools for generating R colors and palettes.

- Plotting functions: `plotBed()`, `plotBedgraph()`, `plotBedpe()`, `plot-Genes()`, `plotHiC()`, and `plotManhattan()`

- Annotating functions: `labelgenome()` and `addlegend()`

- Zooming functions: `zoomsregion()` and `zoombox()`

- Coloring functions: `maptocolors()`, `SushiColors()`, and `opaque()`

3.2 Non-Sushi Functions

An important characteristic of Sushi plots is their compatibility with all base R functions and their ability to be combined into complex multipanel figures. Two of the most usefule base R functions for creating multipanel figures are `layout()` and `mfrow()`. Basic R plotting functions such as `axis()`, `mtext()`, and `legend()` are also particularly well suited to combine with Sushi plots. A familiarity with these functions will greatly improve your ability to create Sushi plots.

3.3 plotBedgraph

Signal tracks can be plotted using `plotBedgraph()`. The input requires data in bedgraph format. We will demonstrate this using bedgraph data representing a DNaseI hypersensitivity experiment in K562 cells.

```
>    head(Sushi_DNaseI.bedgraph)

  chrom    start      end value
1 chr11 1640504 1640664     1
2 chr11 1640904 1641004     1
3 chr11 1641004 1641064     2
4 chr11 1641064 1641164     1
5 chr11 1645224 1645384     1
6 chr11 1645504 1645664     1
```

The `plotBedgraph()` function is used to plot the data. As with most Sushi functions the basic required arguments include the data to be plotted, the chromosome, and a start and stop position.

```
> chrom           = "chr11"
> chromstart      = 1650000
> chromend        = 2350000
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart,chromend,colorbycol= SushiColors(5))
```

To annotate the genome postion we use the `labelgenome()` function. We us `n` = 4 to specify the desired number of tickmarks. The scale is set to `Mb` (other options are `Kb` or `bp`).

```
> labelgenome(chrom,chromstart,chromend,n=4,scale="Mb")
```

The y-axis can be added using basic R functions `mtext()` and `axis()`.

```
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
```

Multiple bedgraph tracks can be plotted on the same plot by setting `overlay=TRUE`. Transparencies can be added for easier viewing by adjusting the transcparency value. The second plot can be rescaled to the maximum of the first plot by setting `rescaleoverlay=TRUE`.

```
> chrom            = "chr11"
> chromstart       = 1955000
> chromend         = 1960000
> plotBedgraph(Sushi_ChIPSeq_CTCF.bedgraph,chrom,chromstart,chromend,
              transparency=.50,color=SushiColors(2)(2)[1])
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart,chromend,
              transparency=.50,color=SushiColors(2)(2)[2],overlay=TRUE,
              rescaleoverlay=TRUE)
> labelgenome(chrom,chromstart,chromend,n=3,scale="Kb")
```
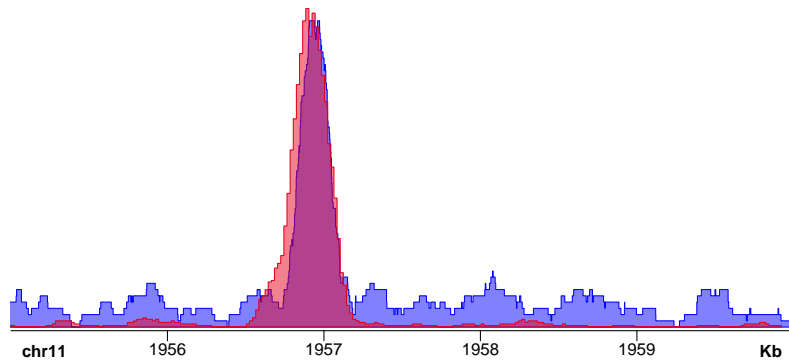

Then we can use the base R function `legend()` to add a legend to the plot. First we need to use the rgb function to add transparency to the colors in order to match out plot.

```
> legend("topright",inset=0.025,legend=c("DNaseI","ChIP-seq (CTCF)"),
        fill=opaque(SushiColors(2)(2)),border=SushiColors(2)(2),text.font=2,
        cex=1.0)
```

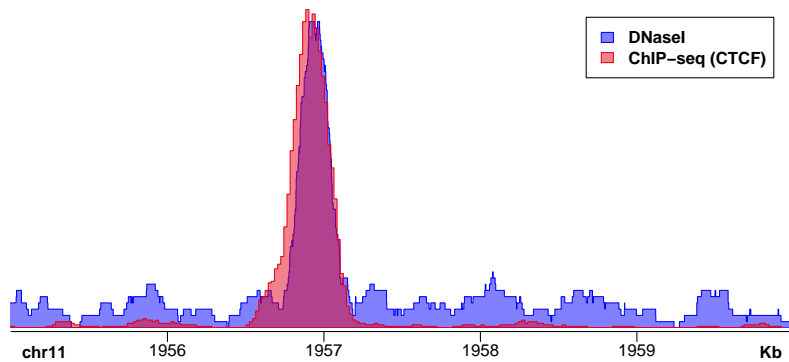

Setting `flip=TRUE` is another method that can be used to compare tracks. First, we will use mfrow to divided the plotting divice into two vertically stacked regions.

```
> par(mfrow=c(2,1),mar=c(1,4,1,1))
```

8

Next, we plot the first plot. We set the transparency of the plot to 0.5. We will
also add the legend.

```
> plotBedgraph(Sushi_ChIPSeq_CTCF.bedgraph,chrom,chromstart,chromend,transparency=.50,
                color=SushiColors(2)(2)[1])
> axis(side=2,las=2,tcl=.2)
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> legend("topright",inset=0.025,legend=c("DNaseI","ChIP-seq (CTCF)"),
          fill=opaque(SushiColors(2)(2)),border=SushiColors(2)(2),text.font=2,
          cex=1.0)
```

Finally, we add the second plot with `flip=TRUE`. We will also label the x-axis
using `labelgenome()` and label the y-axis using `mtext()` and `axis()`.

```
> plotBedgraph(Sushi_DNaseI.bedgraph, chrom, chromstart, chromend,
                transparency=.50, flip=TRUE, color=SushiColors(2)(2)[2])
> labelgenome(chrom,chromstart,chromend,side=3,n=3,scale="Kb")
```

```
> axis(side=2,las=2,tcl=.2,at=pretty(par("yaxp")[c(1,2)]),
                labels=-1*pretty(par("yaxp")[c(1,2)]))
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
```

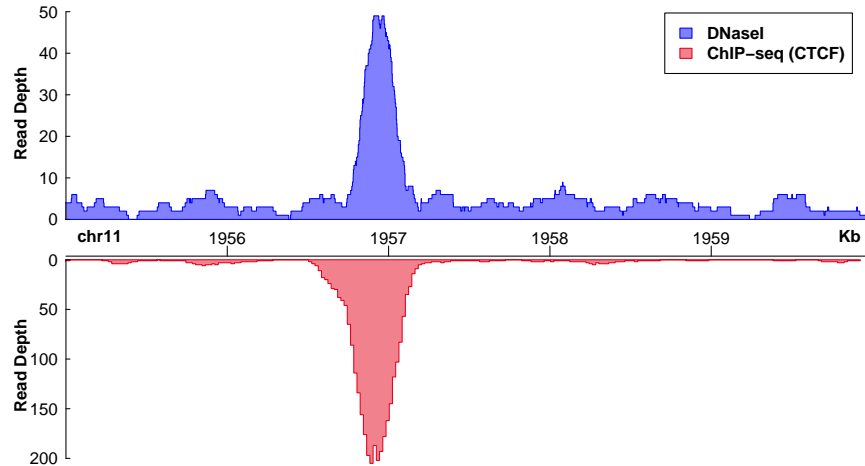

3.4 plotHic

HiC interaction plots can be plotted given an interaction matrix in which row
and column names are genomic coordiates and matrix values are some tye of
interaction score.

```
>    Sushi_HiC.matrix[100:105,100:105]

          4460000  4500000  4540000  4580000   4620000  4660000
4460000 60.758775 18.84723 33.31506 22.56641  7.926361 10.69235
4500000 18.847231 32.56282 36.31212 29.04343 13.375643 12.67360
4540000 33.315060 36.31212 17.97024 43.43753 20.411952 16.98875
4580000 22.566409 29.04343 43.43753 38.93754 25.206417 23.87764
4620000  7.926361 13.37564 20.41195 25.20642  9.201501 38.33665
4660000 10.692351 12.67360 16.98875 23.87764 38.336646 22.55054
```

The `plotHic()` function is used to plot the data while the `labelgenome()` func-
tion is used to add the genome labels to the x-axis. `plotHic()` returns an object
indicating the color palette and data range that can be fed into `addlegend()`
to create a legend.

```
> chrom             = "chr11"
> chromstart        = 500000
> chromend          = 5050000
> phic = plotHic(Sushi_HiC.matrix, chrom,chromstart, chromend, max_y = 20,
                zrange=c(0,28), palette=SushiColors(7))
```

10

```
> addlegend(phic[[1]], palette=phic[[2]], title="score", side="right",
            bottominset=0.4, topinset=0, xoffset=-.035, labelside="left",
            width=0.025, title.offset=0.035)
> labelgenome(chrom, chromstart, chromend, n=4, scale="Mb",
              edgeblankfraction=0.20)
```

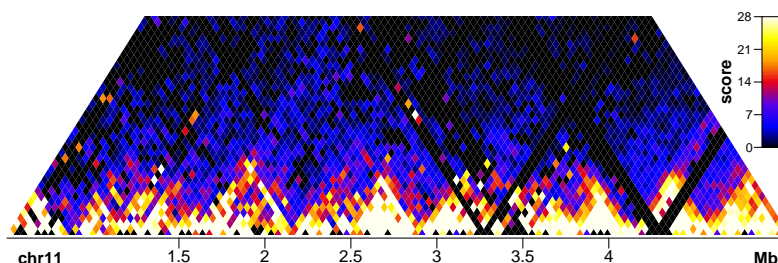

plotHic() has a number of customizable options. The plot can be flipped over
the x-axis by setting flip = TRUE. The color palette can be changed by the
palette argument.

addlegend() also has customizable features. The legend can be moved to the
left side of the plot by setting side = "left" and the labeling can be moved
to the right side of the lenged buy setting labelside = "right". The vertical
position of the legend can be adjusted by changing the topinset and bottomin-
set.

Finally, the x-axis label can be moved to the top of the plot by setting side =
3 in the labelgenome() function.

```
> chrom              = "chr11"
> chromstart         = 500000
> chromend           = 5050000
> phic = plotHic(Sushi_HiC.matrix,chrom,chromstart,chromend,max_y = 20,
                 zrange=c(0,28),flip=TRUE,palette=topo.colors)
> addlegend(phic[[1]],palette=phic[[2]],title="score",side="left",bottominset=0.1,
            topinset=0.5,xoffset=-.035,labelside="right",width=0.025,title.offset=0.035)
> labelgenome(chrom,chromstart,chromend,side=3,n=4,scale="Mb",edgeblankfraction=0.20)
```

3.5   plotBedpe

plotBedpe() allows for data in bedpe format to be plotted in multiple fashions. To illustrate this we will use 5C data formatted in the following way.

```
>    head(Sushi_5C.bedpe)
```

```
  chrom1     start1        end1 chrom2     start2        end2 name    score strand1
1   chr2 234208447 234223064   chr2 234156762 234159135   NA 44.39862       .
2  chr15  41711734  41718116  chr15  41802421  41808201   NA 20.62534       .
3  chr11  64172456  64183193  chr11  64068878  64079209   NA 16.91630       .
4   chr2 234208447 234223064   chr2 234163674 234170252   NA 12.34501       .
5   chr6  41755186  41769245   chr6  41435903  41452283   NA 11.63480       .
6  chr11  64159283  64172456  chr11  64068878  64079209   NA 11.13098       .
  strand2 samplenumber
1       .            1
2       .            1
3       .            1
4       .            1
5       .            1
6       .            1
```

plotBedpe() can plot bedpe as arches. The height, linewidth, and color of each arch can be scaled to represent different aspects of the data. Here the height of the arches represents the Z-score of the 5C interaction, the color represents the cell line each interaction was detected in, and the line widths are kept constant (default lwd = 1).

```
> chrom            = "chr11"
> chromstart       = 1650000
> chromend         = 2350000
> pbpe = plotBedpe(Sushi_5C.bedpe,chrom,chromstart,chromend,
                 heights = Sushi_5C.bedpe$score,plottype="loops",
```

```
                        colorby=Sushi_5C.bedpe$samplenumber,
                        colorbycol=SushiColors(3))
> labelgenome(chrom, chromstart,chromend,n=3,scale="Mb")
> legend("topright",inset =0.01,legend=c("K562","HeLa","GM12878"),
        col=SushiColors(3)(3),pch=19,bty='n',text.font=2)
> axis(side=2,las=2,tcl=.2)
> mtext("Z-score",side=2,line=1.75,cex=.75,font=2)
```

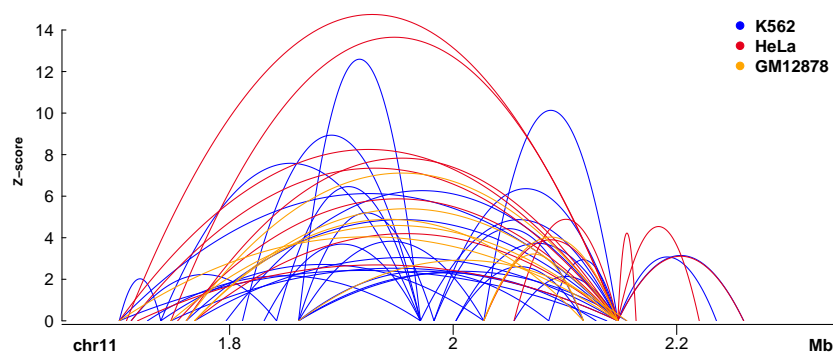

The plot can be flipped over the x-axis by setting `flip = TRUE`, Bedpe elements can be represented by boxes and straight lines by setting `plottype = "lines"`. And colors can be used to represent Z-scores by setting `colorby = "Sushi_5C.bedpe$score"`.

```
> chrom             = "chr11"
> chromstart        = 1650000
> chromend          = 2350000
> pbpe = plotBedpe(Sushi_5C.bedpe,chrom,chromstart,chromend,flip=TRUE,
                   plottype="lines",colorby=Sushi_5C.bedpe$score,
                   colorbycol=SushiColors(5))
> labelgenome(chrom, chromstart,chromend,side=3,n=3,scale="Mb")
> addlegend(pbpe[[1]],palette=pbpe[[2]],title="Z-score",side="right",bottominset=0.05,
           topinset=0.05,xoffset=-.035,labelside="right",width=0.025,title.offset=0.045)
```
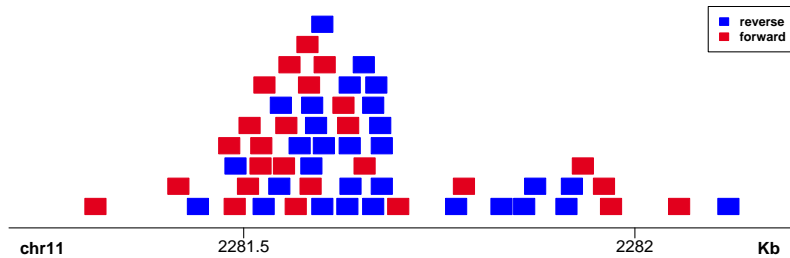

3.6 plotBed

`plotBed` provides multiple different ways to represent genomic data stored in bed format. Below are the first six lines of a bed file detailing reads from Pol2 ChIP-Seq analysis of K562 cells.

```
> head(Sushi_ChIPSeq_pol2.bed)
```

```
  chrom    start      end                          name score strand
1 chr11 2280543 2280570 GGGCTCTCTCCGGCTTCCCTGTCCCGT    63     -1
2 chr11 2288946 2288973 CCTTCCCATCCGCAGGGGCACCACATG  1000     -1
3 chr11 2272471 2272498 TGGGCATCAGTCAGGCTCCTTCCCCAG  1000     -1
4 chr11 2288939 2288966 ATCCGCAGGGGCACCACATGAGTCACC  1000     -1
5 chr11 2281534 2281561 TGTCCTAGTGACAAGTGGCCGGACTTG   250     -1
6 chr11 2286805 2286832 GGTGAGGGCCAGCAGCTCCCTGGGGGG   250      1
```

Leaving row set to `auto` provides a pile-sup style plot. Here the `colorby` argument is used to color the bed elements by the strand.

```
> chrom            = "chr11"
> chromstart       = 2281200
> chromend         = 2282200
> plotBed(beddata    = Sushi_ChIPSeq_pol2.bed,chrom = chrom,chromstart = chromstart,
          chromend =chromend,colorby     = Sushi_ChIPSeq_pol2.bed$strand,
          colorbycol = SushiColors(2),row  = "auto",wiggle=0.001)
> labelgenome(chrom,chromstart,chromend,n=2,scale="Kb")
> legend("topright",inset=0,legend=c("reverse","forward"),fill=SushiColors(2)(2),
          border=SushiColors(2)(2),text.font=2,cex=0.75)
```

Setting `splitstrand = TRUE` plots reads from different strands in two separate
vertical regions.

```
> chrom            = "chr11"
> chromstart       = 2281200
> chromend         = 2282200
> plotBed(beddata    = Sushi_ChIPSeq_pol2.bed,chrom = chrom,chromstart = chromstart,
          chromend =chromend,colorby     = Sushi_ChIPSeq_pol2.bed$strand,
          colorbycol = SushiColors(2),row  = "auto",wiggle=0.001,splitstrand=TRUE)
> labelgenome(chrom,chromstart,chromend,n=2,scale="Kb")
> legend("topright",inset=0,legend=c("reverse","forward"),fill=SushiColors(2)(2),
          border=SushiColors(2)(2),text.font=2,cex=0.75)
```

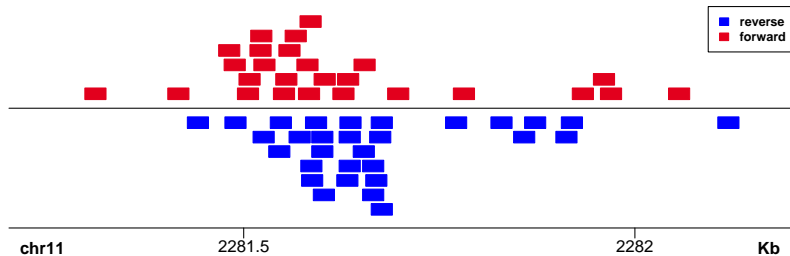

plotBed can also plot bed elements on different rows as specified by the user.
First, we will use the Sushi function `maptocolors()` to assign a different color
to each row.

```
> Sushi_ChIPSeq_severalfactors.bed$color =
          maptocolors(Sushi_ChIPSeq_severalfactors.bed$row,
          col=SushiColors(6))
```

15

By providing row and color information `plotBed()` can be used to compare bed elements from different samples by plotting them on different rows.

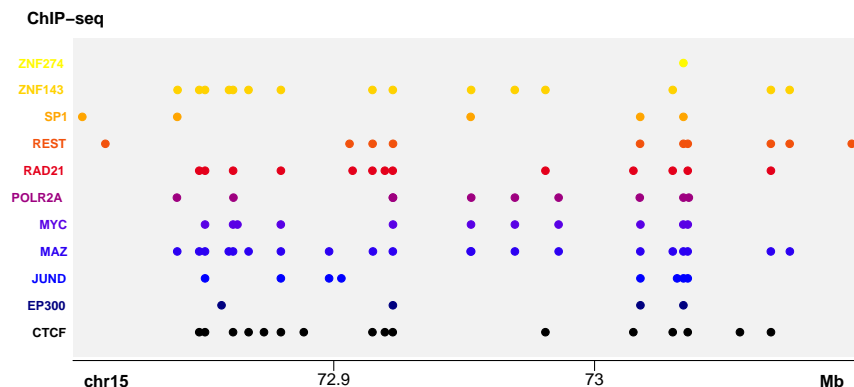

```
> chrom            = "chr15"
> chromstart       = 72800000
> chromend         = 73100000
> plotBed(beddata     = Sushi_ChIPSeq_severalfactors.bed,chrom = chrom,
          chromstart = chromstart,chromend =chromend,
          rownumber  = Sushi_ChIPSeq_severalfactors.bed$row, type = "circles",
          color=Sushi_ChIPSeq_severalfactors.bed$color,row="given",
          plotbg="grey95",rowlabels=unique(Sushi_ChIPSeq_severalfactors.bed$name),
          rowlabelcol=unique(Sushi_ChIPSeq_severalfactors.bed$color),rowlabelcex=0.75)
> labelgenome(chrom,chromstart,chromend,n=3,scale="Mb")
> mtext("ChIP-seq",side=3, adj=-0.065,line=0.5,font=2)
```

That same data can be represented by rectangles that depict the actual width of each bed element.

```
> plotBed(beddata     = Sushi_ChIPSeq_severalfactors.bed,chrom = chrom,
          chromstart = chromstart,chromend =chromend,
          rownumber  = Sushi_ChIPSeq_severalfactors.bed$row, type = "region",
          color=Sushi_ChIPSeq_severalfactors.bed$color,row="given",
          plotbg="grey95",rowlabels=unique(Sushi_ChIPSeq_severalfactors.bed$name),
          rowlabelcol=unique(Sushi_ChIPSeq_severalfactors.bed$color),rowlabelcex=0.75)
> labelgenome(chrom,chromstart,chromend,n=3,scale="Mb")
> mtext("ChIP-seq",side=3, adj=-0.065,line=0.5,font=2)
```

16
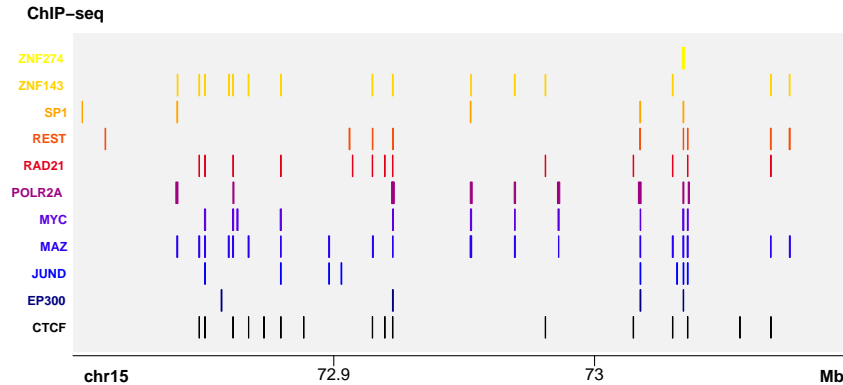

plotBed() can also be used to plot heatmaps representing the density of bed elements. First, we will use the biomaRt function getBM() to get the gene information we require.

```
> chrom            = "chr15"
> chromstart       = 60000000
> chromend         = 80000000
> chrom_biomart    = gsub("chr","",chrom)
> mart=useMart(host='may2009.archive.ensembl.org', biomart='ENSEMBL_MART_ENSEMBL',
               dataset='hsapiens_gene_ensembl')
> geneinfobed = getBM(attributes = c("chromosome_name","start_position","end_position"),
                   filters= c("chromosome_name","start","end"),
                   values=list(chrom_biomart,chromstart,chromend),mart=mart)
> geneinfobed[,1] = paste("chr",geneinfobed[,1],sep="")
```

The data is in simple bed format with just three columns representing chromosome, start, and stop.

```
> head (geneinfobed)

  chromosome_name start_position end_position
1          chr15       73372069     73372334
2          chr15       64580642     64580710
3          chr15       63375442     63375557
4          chr15       72570353     72570422
5          chr15       60903209     60903293
6          chr15       70130646     70130724
```

Now we can make a gene density plot using the plotBed function.

17

```
> plotBed(beddata = geneinfobed[!duplicated(geneinfobed),],chrom = chrom,
          chromstart = chromstart,chromend =chromend,row='supplied',
          palettes = list(SushiColors(7)), type = "density")
> labelgenome(chrom, chromstart, chromend,  n=4,scale="Mb",edgeblankfraction=0.10)
> mtext("Gene Density",side=3, adj=0,line=0.20,font=2)
```

Gene Density
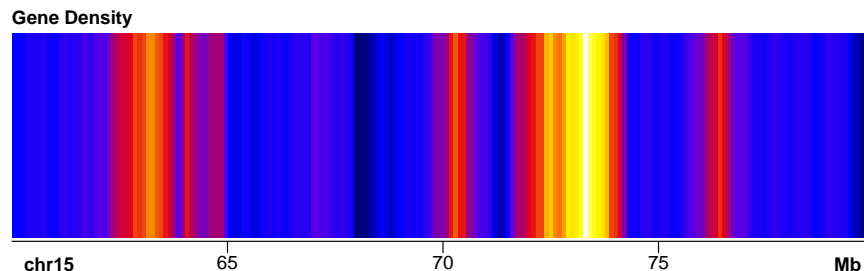

3.7   plotManhattan

`plotManhattan()` differs from most other Sushi functions in that it can plot
multiple chromosomes in a single plot. Because of this plotManhattan requires
some additional inputs. It requires an object in bed format describing the
location of data points as well as vector of p-values (typically one of the columns
of the bed file). But it also requires an genome object that describes which
chromosomes to plot and their sizes (in bp). The genome object is very similar
to the genome files used for bedtools.

The bed data should look something like this:

```
>   head(Sushi_GWAS.bed)
```

```
  chr.hg18 pos.hg18 pos.hg18.1       rsid pval.GC.DBP V6
1     chr1  1695996    1695996  rs6603811    0.003110  .
2     chr1  1696020    1696020  rs7531583    0.000824  .
3     chr1  1698661    1698661 rs12044597    0.001280  .
4     chr1  1711339    1711339  rs2272908    0.001510  .
5     chr1  1712792    1712792  rs3737628    0.001490  .
6     chr1  1736016    1736016 rs12408690    0.004000  .
```

And the genome file should look like this:

```
>   head(Sushi_hg18_genome)
```

```
     V1         V2
1  chr1 247249719
2 chr10 135374737
```

```
3 chr11 134452384
4 chr12 132349534
5 chr13 114142980
6 chr14 106368585
```

The `plotManhattan()` function is used to plot the data while the `labelgenome()` function is used to add the genome labels to the x-axis. The `labelgenome()` function also requires a genome object.

```
> plotManhattan(bedfile=Sushi_GWAS.bed,pvalues=Sushi_GWAS.bed[,5],
                col=SushiColors(6),genome=Sushi_hg18_genome,cex=0.75)
> labelgenome(genome=Sushi_hg18_genome,n=4,scale="Mb",
                edgeblankfraction=0.20,cex.axis=.5)
> axis(side=2,las=2,tcl=.2)
> mtext("log10(P)",side=2,line=1.75,cex=1,font=2)
> mtext("chromosome",side=1,line=1.75,cex=1,font=2)
```

```
pdf
  2
```

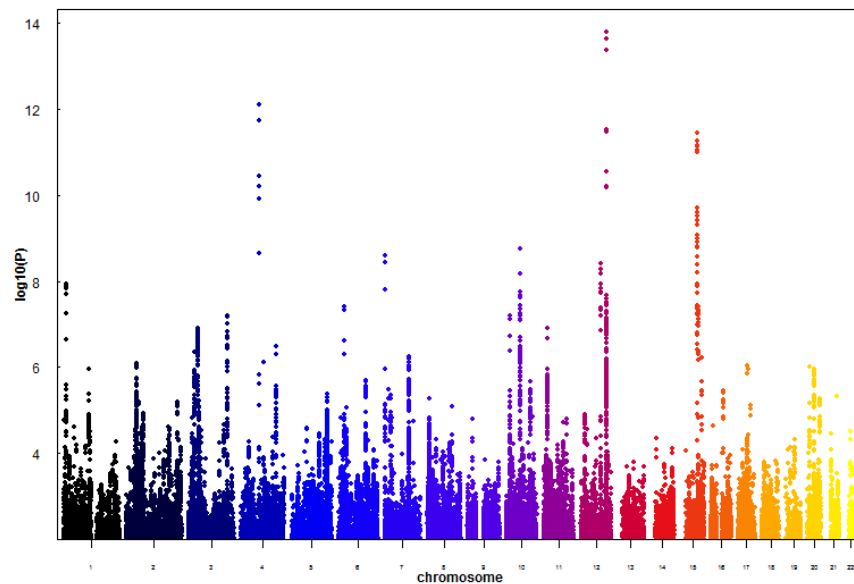

3.8   plotGenes

`plotGenes()` can be used to plot gene structures that are stored in bed format. If no `geneinfo` object is provided genes are looked up in the region using biomart with biomart='ensembl' and dataset='hsapiens_gene_ensembl'.

```
> head(Sushi_genes.bed)

  chrom    start     stop  gene score strand
1 chr15 73017309 73017438 COX5A    .     -1
2 chr15 72999672 72999836 COX5A    .     -1
3 chr15 73003042 73003164 COX5A    .     -1
4 chr15 73006160 73006281 COX5A    .     -1
5 chr15 73008510 73008626 COX5A    .     -1
```

Using `plotGenes()` with arguments `bentline=FALSE` and `plotgenetype="arrow"`
produces arrow and line gene structures.

```
> chrom           = "chr15"
> chromstart      = 72998000
> chromend        = 73020000
> pg = plotGenes(Sushi_genes.bed,chrom,chromstart,chromend ,
             types=Sushi_genes.bed$type,maxrows=1,bheight=0.2,
             plotgenetype="arrow",bentline=FALSE,
         labeloffset=.4,fontsize=1.2,arrowlength = 0.025,
             labeltext=TRUE)
> labelgenome( chrom, chromstart,chromend,n=3,scale="Mb")
```

This function can also be used to plot transcript structures. The first 20 lines
of a data frame describing RNA seq data are shown below.

```
> Sushi_transcripts.bed[1:20,]

  chrom    start     stop              gene     score strand type
1 chr15 73062668 73062770 ENST00000362710  0.000000     -1 exon
2 chr15 73097788 73097929 ENST00000361900  0.000000      1 exon
3 chr15 73097264 73097365 ENST00000361900  0.000000      1 exon
4 chr15 73095987 73096143 ENST00000361900  0.000000      1 exon
5 chr15 73092071 73092199 ENST00000361900  0.000000      1 exon
6 chr15 73091234 73091240 ENST00000361900  0.000000      1 exon
7 chr15 73017309 73017408 ENST00000322347 31.488695     -1 exon
8 chr15 73006160 73006281 ENST00000322347 31.488695     -1 exon
```

```
9  chr15 73008510 73008626 ENST00000322347 31.488695   -1 exon

12 chr15 72985672 72985759 ENST00000357635 7.473977    -1 exon
13 chr15 72985981 72986194 ENST00000357635 7.473977    -1 exon
14 chr15 72975546 72975719 ENST00000379693 2.422616     1 exon
15 chr15 72972532 72972714 ENST00000379693 2.422616     1 exon
16 chr15 72972055 72972196 ENST00000379693 2.422616     1 exon
17 chr15 72970773 72970973 ENST00000379693 2.422616     1 exon
18 chr15 72969965 72970048 ENST00000379693 2.422616     1 exon
19 chr15 72972532 72972714 ENST00000352410 0.917141     1 exon
20 chr15 72972055 72972196 ENST00000352410 0.917141     1 exon
```

A vector `type` can be used to specify if each region is an 'exon' or 'utr' while `plotgenetype="box"` plots regions as a boxes rather than arrows. The data can be plotted using `plotGenes()`. The `colorby` argument is used to color the transcripts by log 10(FPKM). UTR regions are drawn as shorter boxes than exons.

```
> chrom          = "chr15"
> chromstart     = 72965000
> chromend       = 72990000
> pg = plotGenes(Sushi_transcripts.bed,chrom,chromstart,chromend ,
               types = Sushi_transcripts.bed$type,
               colorby=log10(Sushi_transcripts.bed$score+0.001),
               colorbycol= SushiColors(5),colorbyrange=c(0,1.0),
               labeltext=TRUE,maxrows=50,height=0.4,plotgenetype="box")
> labelgenome( chrom, chromstart,chromend,n=3,scale="Mb")
> addlegend(pg[[1]],palette=pg[[2]],title="log10(FPKM)",side="right",
          bottominset=0.4,topinset=0,xoffset=-.035,labelside="left",
          width=0.025,title.offset=0.055)
```

3.9 Zoom functions

A critical characteristic of the Sushi package is its ability to create highly customizable, publication-ready, multi-panel figures. Here, we will create a basic three panel figure and demonstrate how the zoom functions work (`zoomsregion` and `zoombox`). To illustrate these feature we will use the `plotBedgraph()` function to plot bedgrpah data representing a DNaseI hypersensitivity experiment in K562 cells.

In order to make a multipanel figure we will use the R function layout. Layout divides the device into rows and columns accoriding to a matrix you provide. The matrix also tells it which plots will appear on which parts of the plotting device. Below we make a 2 by 2 matrix. The entire top row will be used to plot the first plot while the bottom row with contain two plots. For more info on layout try `?layout`.

```
> layout(matrix(c(1,1,2,3),2, 2, byrow = TRUE))
> par(mar=c(3,4,1,1))
```

Next we will add the first plot

```
> chrom            = "chr11"
> chromstart       = 1900000
> chromend         = 2350000
```

```
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=chromstart,
               chromend=chromend,colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=chromstart,chromend=chromend,n=4,
              scale="Mb")
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
```

Next we will add the zoom regions using the function zoomsregion(). The
argument offsets is used to precisely position the left and right edges of the
widest part of the zoom.

```
> zoomregion1       = c(1955000,1960000)
> zoomregion2       = c(2279000,2284000)
> zoomsregion(zoomregion1,extend=c(0.01,0.13),wideextend=0.05,
              offsets=c(0,0.580))
> zoomsregion(zoomregion2,extend=c(0.01,0.13),wideextend=0.05,
              offsets=c(0.580,0))
```

Then we can add each of the zoomed inset regions. For, each region we need execute the zoombox function in order to draw the lines around the new plots.

```
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=zoomregion1[1],
              chromend=zoomregion1[2],colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=zoomregion1[1],chromend=zoomregion1[2],
             n=4,scale="Kb",edgeblankfraction=0.2,cex.axis=.75)
> zoombox()
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=zoomregion2[1],
              chromend=zoomregion2[2],colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=zoomregion2[1],chromend=zoomregion2[2],
             n=4,scale="Kb",edgeblankfraction=0.2,cex.axis=.75)
> zoombox()
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
```
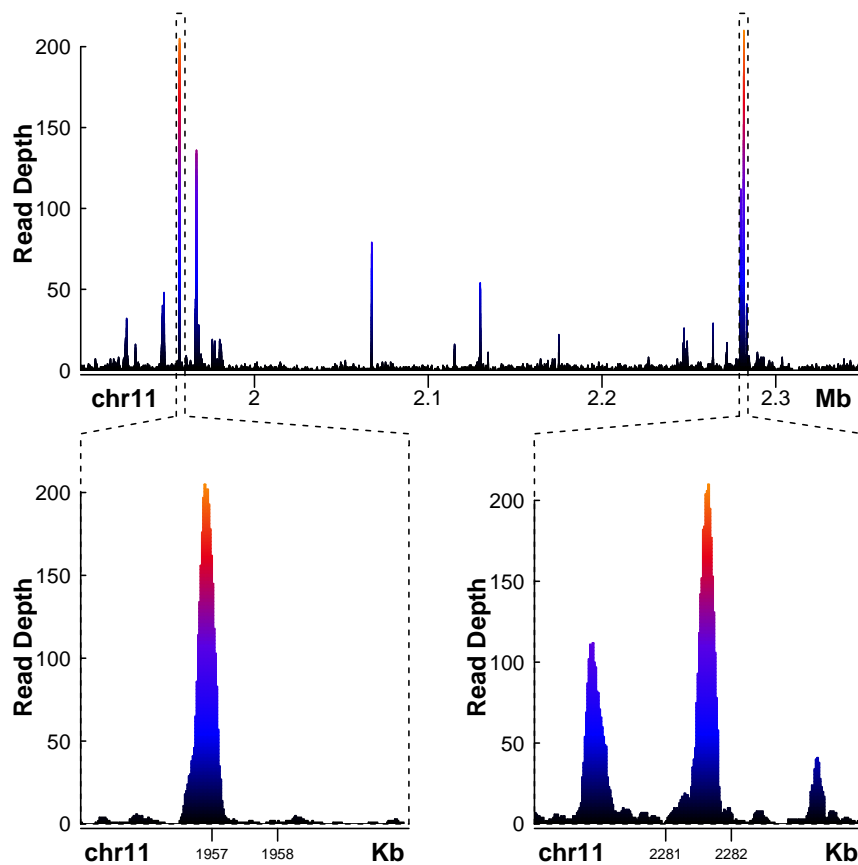

3.10 Color functions

Sushi includes three functions to assist in the generating of R colors and color palettes: `SushiColors()`, `maptocolors()`, `opaque()`.

3.10.1 SushiColors

`SushiColors()` provides default color palettes for the Sushi package.

To see a list of available color palettes:
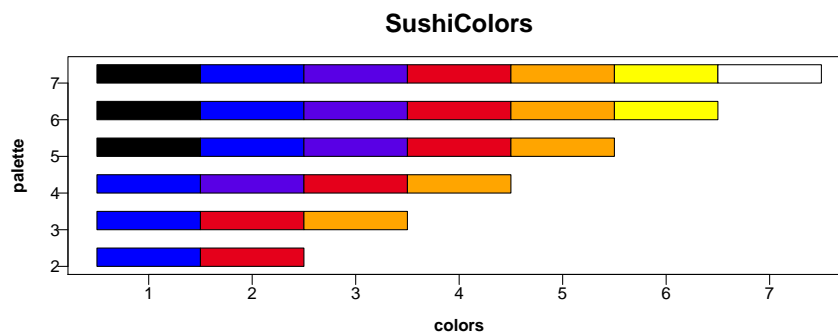

```
> SushiColors(palette='list')
```

```
[1] 2 3 4 5 6 7
```

To view the color palettes:

```
> plot(1,xlab='',xaxt='n',ylab='',yaxt='n',xlim=c(0.5,7.5),
    ylim=c(2,7.5),type='n')
> for (i in (2:7))
 {
   for (j in (1:i))
   {
     rect(j-.5,i,j+.5,i+.5,col=SushiColors(i)(i)[j])
   }
 }
> axis(side=2,at=(2:7),labels=(2:7),las=2)
> axis(side=1,at=(1:7),labels=(1:7))
> mtext("SushiColors",side=3,font=2, line=1, cex=1.5)
> mtext("colors",side=1,font=2, line=2)
> mtext("palette",side=2,font=2, line=2)
```

3.10.2 opaque

opaque() takes any color or vector of colors and makes themp opaque. The
degree of transparency is determined by the argument transparency which is
a value between 0 and 1.

```
> plot(1,xlab='',xaxt='n',ylab='',yaxt='n',bty='n',type='n',
    xlim=c(-.15,1.05),ylim=c(-1,2))
> for (i in seq(0,1,by=0.1))
 {
     rect(i-.05,-1,i+.05,1,col=opaque("red",transparency=i))
     rect(i-.05,0,i+.05,2,col=opaque("blue",transparency=1-i))
 }
> axis(side=1,at=seq(0,1,by=0.1),labels=seq(0,1,by=0.1))
> mtext("red transparency",side=1,font=2, line=2)
> axis(side=3,at=seq(0,1,by=0.1),labels=seq(1,0,by=-0.1))
> mtext("blue transparency",side=3,font=2, line=2)
> text(-0.075,1.5,labels="blue",font=2,adj=1)
```

```
> text(-0.075,0.5,labels="overlap",font=2,adj=1)
> text(-0.075,-.5,labels="red",font=2,adj=1)
```

3.10.3   maptocolors

maptocolors() takes a vector of values and maps them to a color palette which
can be used for plotting.

```
> set.seed(3)
> values = rnorm((1:10))
> colorpalette = SushiColors(5)
> plot(x=(1:10),y=values,col=maptocolors(values,colorpalette),
      pch=19,cex=4,xlab="data points",yaxt='n',ylim=range(values)*1.2)
> addlegend(range(values),title="key",palette=colorpalette,
          side='left',xoffset = -0.125,width=0.03,bottominset = 0.5, topinset = 0.025)
> axis(side=2,las=2)
```

3.11 labeling functions

3.11.1 labelgenome

labelgenome() Add genome coordinates to the x-axis of a plot. The `line` argument can be used to offset the axis and `n` can be used to determine the desired umber of tick marks.

```
> par(mar=c(8,3,3,1),mgp=c(3, .3, 0))
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom="chr11",chromstart=1650000,
              chromend=2350000,colorbycol=SushiColors(7))
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=4,scale="Mb",line=.25)
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=3,scale="Kb",line=2)
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=1,scale="bp",line=4)
```
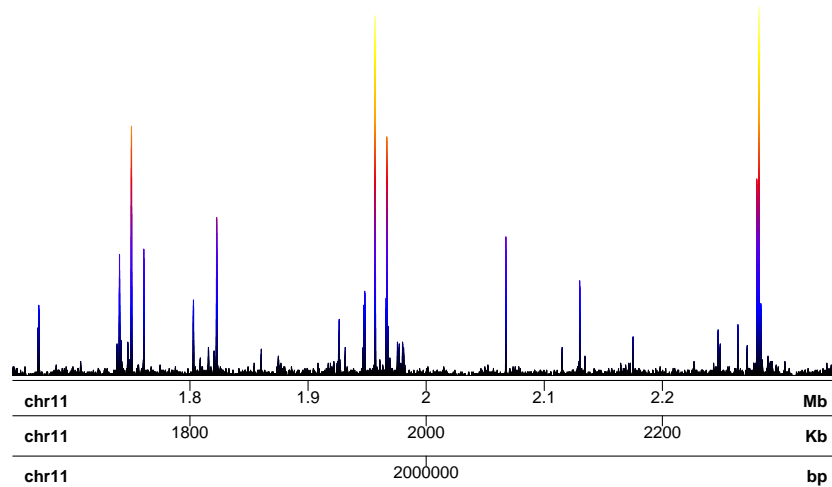

Manhattan plots include multiple genomes and labeling the axes of Manhattan plots requires the same `genome` oject and value of `space` that were used to in `plotManhattan()`

```
> plotManhattan(bedfile=Sushi_GWAS.bed,pvalues=Sushi_GWAS.bed[,5],
                col=SushiColors(6),genome=Sushi_hg18_genome,
                cex=0.75,space=0.05)
> labelgenome(genome=Sushi_hg18_genome,n=4,scale="Mb",
              edgeblankfraction=0.20,cex.axis=.5,space=0.05)
> axis(side=2,las=2,tcl=.2)
> mtext("log10(P)",side=2,line=1.75,cex=1,font=2)
> mtext("chromosome",side=1,line=1.75,cex=1,font=2)

pdf
  2
```
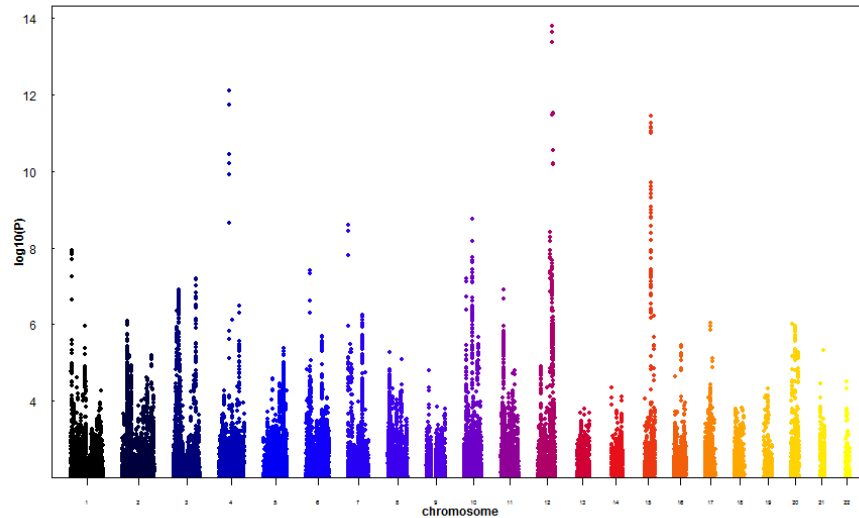

3.11.2 labelplot

Plot labels and titles can be added with the `labelplot()` function.

```
> labelplot("A) ","Manhattan Plot")

> plotManhattan(bedfile=Sushi_GWAS.bed,pvalues=Sushi_GWAS.bed[,5],
                col=SushiColors(6),genome=Sushi_hg18_genome,
                cex=0.75,space=0.05)
> labelgenome(genome=Sushi_hg18_genome,n=4,scale="Mb"
              ,edgeblankfraction=0.20,cex.axis=.5,space=0.05)
> axis(side=2,las=2,tcl=.2)
> mtext("log10(P)",side=2,line=1.75,cex=1,font=2)
> mtext("chromosome",side=1,line=1.75,cex=1,font=2)
> labelplot("A) ","Manhattan Plot")

pdf
  2
```
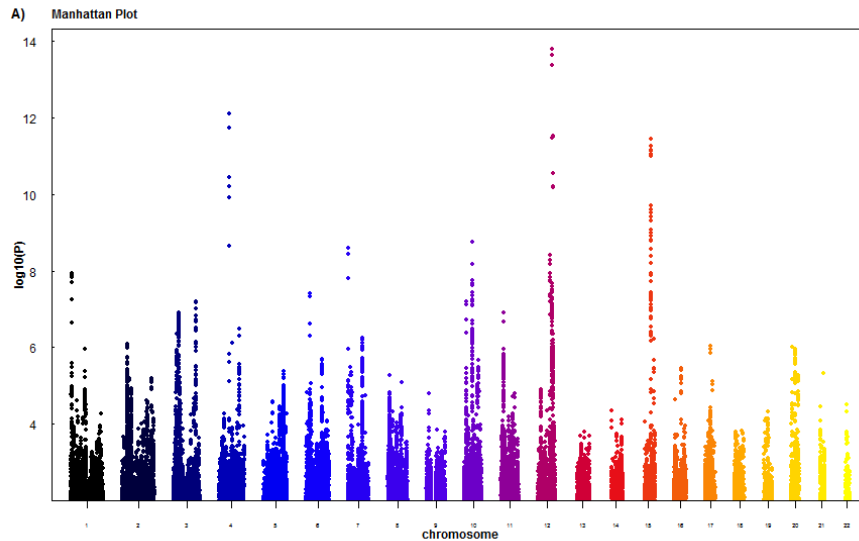

```
[1] FALSE
```

4 Tips

Other popular file formats such as BAM and GFF are not explicitly supported
by Sushi. However, data stored in these formats can be easily converted to BED
format using common command line tools such as the `bedtools` software suite
available at https://github.com/arq5x/bedtools2. Some examples taken from
the `bedtools` are shown below.

Convert BAM alignments to BED format.

```
bamToBed -i reads.bam > reads.bed
```

Convert BAM alignments to BED format using edit distance (NM) as the BED
`score`.

```
bamToBed -i reads.bam -ed > reads.bed
```

Convert BAM alignments to BEDPE format.

```
bamToBed -i reads.bam -bedpe > reads.bedpe
```

These BED files can easily be read into R for use with Sushi using the following
R command:

```
> read.table(file="reads.bed",sep="\t")
```

5 Appendix

For illustrative purposes we include a complex figure as published in the accompanying manuscript (Phanstiel, et al.).

```
1   library('Sushi')
2   pdfname = "vignettes/Figure_1.pdf"
3   Sushi_data = data(package = 'Sushi')
4   data(list = Sushi_data$results[,3])
5   makepdf = TRUE
6
7   ###
8   ### CODE
9   ###
10
11  if (makepdf == TRUE)
12  {
13      pdf(pdfname, height=10, width=12)
14  }
15
